

1. From the desk of Localization

The QA team asked for a one-page smoke test that proves each of our supported locales survives the typesetting pipeline with diacritics intact. We declined to write the poetry ourselves. The national pangrams already do it better, and they are, for tax-residency reasons, the property of no one.

Polski. *Zażółć gęślą jaźń.* Łódź leży nad Wisłą, a Kraków nie. Pchnąć w tę łódź jeża lub ośm skrzyń fig. The second sentence is, we are reliably informed, a tongue-twister. We have not verified it ourselves and we are not going to.

Čeština. *Příliš žluťoučký kůň úpěl ďábelské ódy.* Vrh syn trh. The horse, we gather, was too yellow. The reviewer who suggested this pangram did not elaborate.

Magyar. *Árvízűrő tükrőfúrógép.* Egy hűtlen vejét fülöncsípő, dühös mexikói úr. The first phrase translates, literally, to "flood-resistant mirror-drilling machine." We have decided not to ask. The second phrase introduces an angry Mexican gentleman pinching his unfaithful son-in-law's ear, which seems, all things considered, like a reasonable response.

Română. *Bună ziua! Măine plec la mare cu fătul meu.* QA flagged this one specifically. Romanian's comma-below diacritics (ț, ș) have historically rendered as Turkish-style cedillas (ṭ, ṣ) when the reader's font substitutes Helvetica and ships only the cedilla form. The embedded Noto Sans path sidesteps that entirely: the comma-below glyphs come from the font we bundled, not from whatever Helvetica clone the reader fell back to.

Matematyka. $2 + 3 - 1 \leq 6$, $\sqrt{16} = 4$, $\partial f / \partial x \neq 0$, $\sum (1..n)$. The $\leq$, $\sqrt{}$, ∂ , $\neq$, and $\sum$ are not part of the Noto Sans Regular cut. They are not part of the *Italic* or **Bold** cuts either. The minus sign U+2212 is, for reasons known only to the Noto Sans design team, present in all three Latin cuts — the lone math stowaway, fully kerned, attending a party it was not invited to. We are not asking why. The rest route — automatically, mid-line, with no `#set text(font: . . .)` ceremony — through the bundled Noto Sans Math cut, which the layout engine selects per-cluster whenever the primary face returns `.notdef`. Latin → Math → Latin happens inside a single visual word without you having to think about it.

If any line above looks wrong to you, copy it out of the PDF and paste it into a text editor. The /ToUnicode CMap is wired through every embedded face, so you will get back exactly the codepoints that went in — diacritics, comma-below, math operators, all of it. If your text editor cannot display them afterwards, that is a conversation between you and your text editor. We are not part of it.

Signed, the Localization Team. Please do not call us. We are in a meeting until further notice.
